Automated seismic interpretation using machine learning and field interpretations

Force Hackathon and Advances of Machine Learning on Subsurface Data Stavanger, September 20 2018

Espen Birger Raknes and Peder Aursand

Background

Goals

- Proof-of-concept study for predicting faults and horizons
- Real data needed to be involved
- Train using human interpretations from multiple fields
 - Exploration and production areas
- Binary sample prediction and pixel-level prediction (segmentation)
- **2D** and **3D** training data

APPROACH Training data work flow overview

AkerBP

APPROACH Neural network: Binary sample prediction

Note: Small version of the VGG architecture (Simonyan and Zisserman, 2014)

APPROACH Neural network: Pixel prediction (image segmentation)

Note: Small version of the SegNet architecture (Badrinarayanan et al., 2015)

RESULTS: FAULT PREDICTION Seismic slice

RESULTS: FAULT PREDICTION Heat map binary prediction

RESULTS: FAULT PREDICTION Heat map pixel prediction

RESULTS: HORIZON PREDICTION Seismic slice

RESULTS: HORIZON PREDICTION Heat map pixel prediction

RESULTS: HORIZON MULTI-FIELD TRAINING Seismic

RESULTS: HORIZON MULTI-FIELD TRAINING Heat map: Trained on one dataset

RESULTS: HORIZON MULTI-FIELD TRAINING Heat map: Trained on another dataset

RESULTS: HORIZON MULTI-FIELD TRAINING Heat map: Trained on two datasets

Discussion and conclusion

Areas are different

- Differences in
 - Geology
 - Data quality
- Number of interpretations varies dependent on where the area is in the development phase

Suggestions

- More data to train on
- Representative data of the geology
- Model adaption to the area to be used on
- Apply techniques for preventing over-fitting

Using human interpretations

- Using human interpretations are not straight forward
- **Many** false negatives
- Very few false positives
- Non-symmetric label noise

Suggestions

- Use synthetic data
- Mix of synthetic and human-made data
- Manually QC-ed human-made data
- Use data from areas with enough interpretations

Straight lines are difficult

- Out-of-the box neural networks with standard loss functions struggle with finding straight lines
 - Learning best on objects with some «extent»
- Standard metrics not ideal

- New and better loss functions
- Take topology into account
- Post processing steps on the heat maps

Conclusion

Summary

- Image recognition by training models on human interpretations projected onto seismic samples
- Features predicted
 - Faults
 - Horizons

Challenges

- Non-symmetric label noise (false negatives) due to incomplete interpretations (manual data quality check is timeconsuming)
- Prediction accuracy suffers when applying a model to a different field
- Standard image recognition is not well suited for detecting lines and planes
- A reference data set for benchmarking these kinds of models is badly needed

Future work

- Transfer learning using pre-trained weights
- 3D data augmentation (transformations on real data or artificial data)
- Better metrics for FCNN
- Train on large combined datasets from multiple fields
- Pre-stack seismic data
